                                                                      302
                                                                            293
                                                                                   259
                                                                                        229
                                                                                              203
                            1955
                                  242
                                        233
                                              267
                                                    269
                                                          270
                                                                 315
                                                                       364
                                                                            347
                                                                                   312
                                                                                        274
                                                                                              237
```

Dec

[9]: class(AirPassengers)

'ts'

[10]: end(AirPassengers)

1. 1960 2. 12

[11]: sum(is.na(AirPassengers))

[12]: frequency(AirPassengers)

```
[13]: summary(AirPassengers)
```

```
Min. 1st Qu. Median Mean 3rd Qu. Max. 104.0 180.0 265.5 280.3 360.5 622.0
```

0.2 TEST THE STATIONARITY OF TIME SERIES

[14]: adf.test(AirPassengers, alternative ="stationary", k=12)

Augmented Dickey-Fuller Test

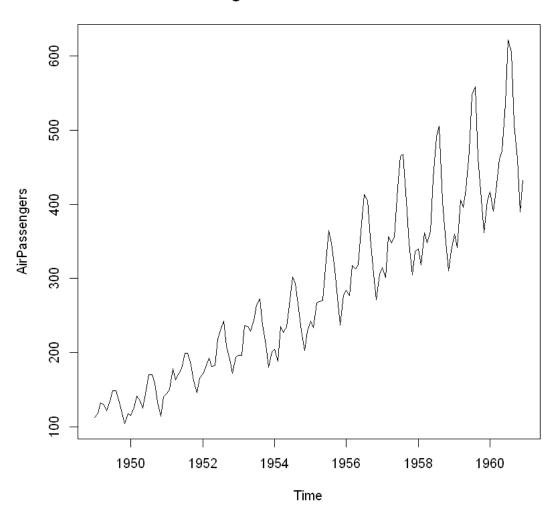

data: AirPassengers

Dickey-Fuller = -1.5094, Lag order = 12, p-value = 0.7807

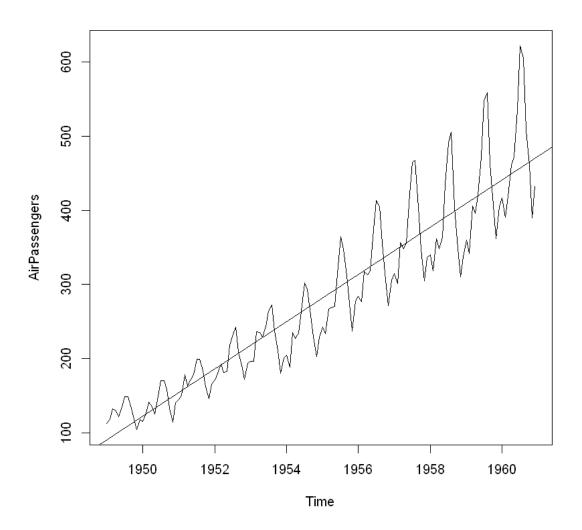

alternative hypothesis: stationary

[15]: plot(AirPassengers, main="Air Passenger numbers from 1949 to 1961") #show_
→sparkine

Air Passenger numbers from 1949 to 1961

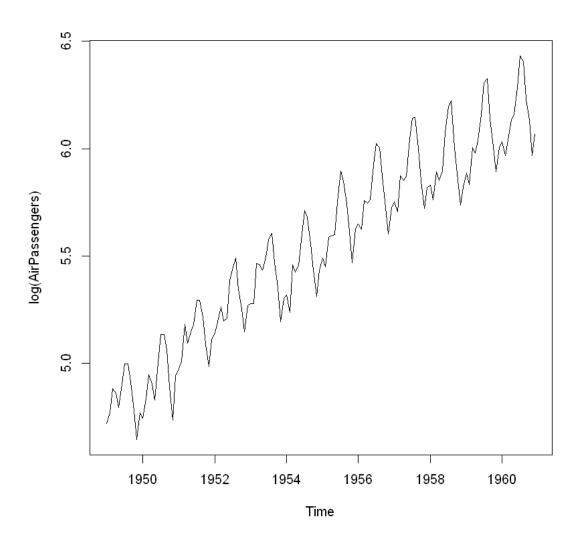

```
[16]: plot(AirPassengers)+abline(reg=lm(AirPassengers~time(AirPassengers)))
```

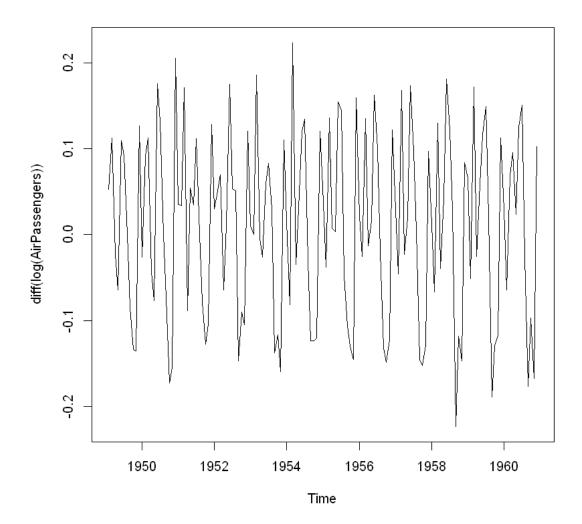

0.3 MAKE IT STATIONARY

[17]: plot(log(AirPassengers))

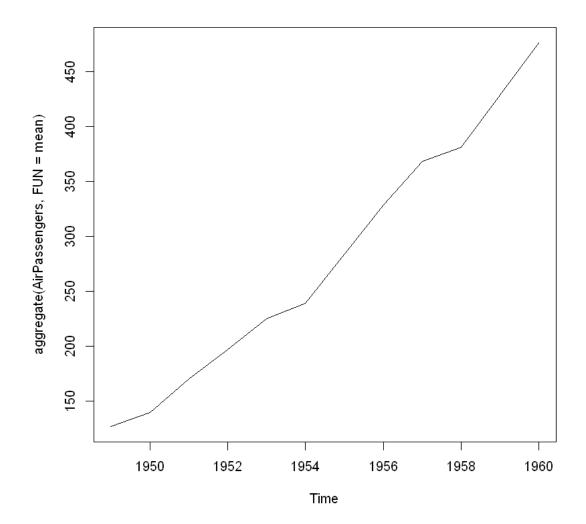

```
[18]: plot(diff(log(AirPassengers)))
```

Now you can see mean and variance both are stationary

0.3.1 Check General Trend

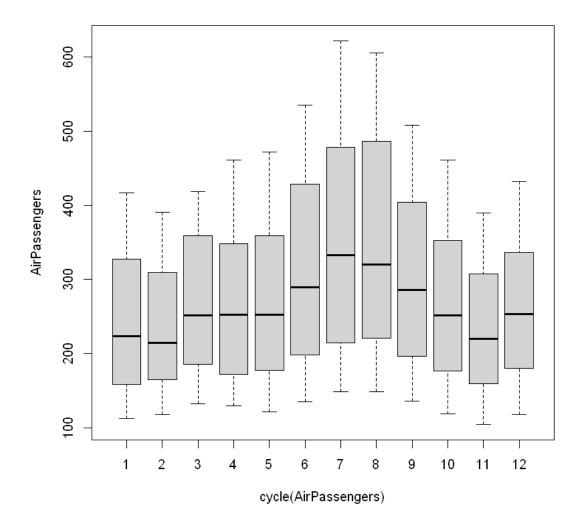

```
[19]: plot(aggregate(AirPassengers, FUN = mean))
```

It is upword trend Use the boxplot function to see any seasonal effects.

0.3.2 show seasonality

```
[20]: boxplot(AirPassengers~cycle(AirPassengers))
```

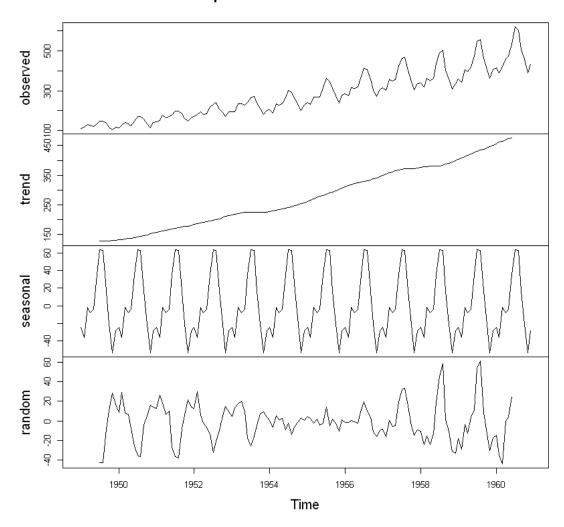

In the boxplot you can see in month july and aug no of passangers traveling are more. The rationale for this could be more people taking holidays and fly over the summer months

0.4 TIME SERIES DECOMPOSITION

```
[21]: plot(decompose(AirPassengers)) # time series decomposition
```

Decomposition of additive time series

The above figure shows the time series decomposition into trend, seasonal and random (noise). It is clear that the time series is non-stationary (has random walks) because of seasonal effects and a trend (linear trend).

0.5 MODEL IDENTIFICATION AND ESTIMATION

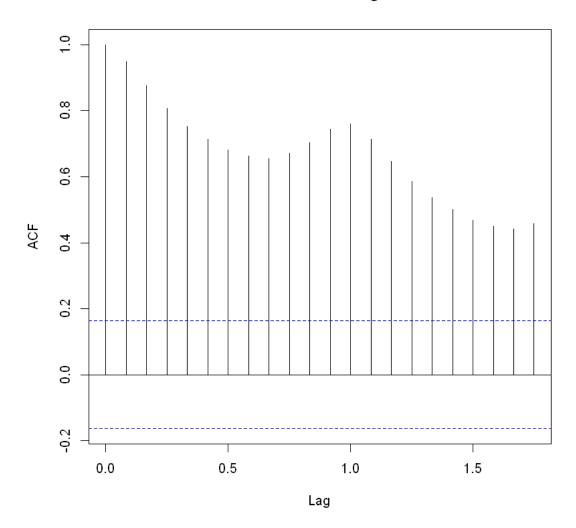

```
[22]: tsdata <- ts(log(AirPassengers), frequency = 12)
```

- . Calculate p d q value
- . AR(Autoregreesive):- by seeing the past value, predict own value Integration
- . $MA(Moving\ Average)$:- you take diff intervals and calculate the average Autocorrelation function and partial autocorrelation function to determine value of p and q

- . Autocorrelation is the linear dependence of a variable with itself at two points in time Auto correlation function, as the word suggests, auto-correlation, means it is really correlation on itself. With time series we just have a single stream of values, or in other words there is just the X no Y.
- . So suppose your time series is like this X = 3,5,6,6,7,4,5,6,7,2,3,4, correlation between 4 and 3, 3 and 2, 2 and 7 (lag 1) will be say y1; correlation between 4 and 2, 3 and 7, 2 and 6 (lag 2) will be say y2; and so on at lags 3 = y3, lag 4 = y4.

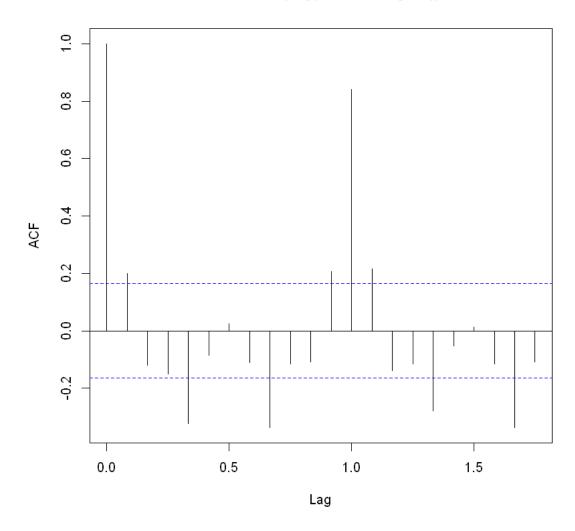

[23]: acf(AirPassengers)

Series AirPassengers

[24]: acf(diff(log(AirPassengers)))

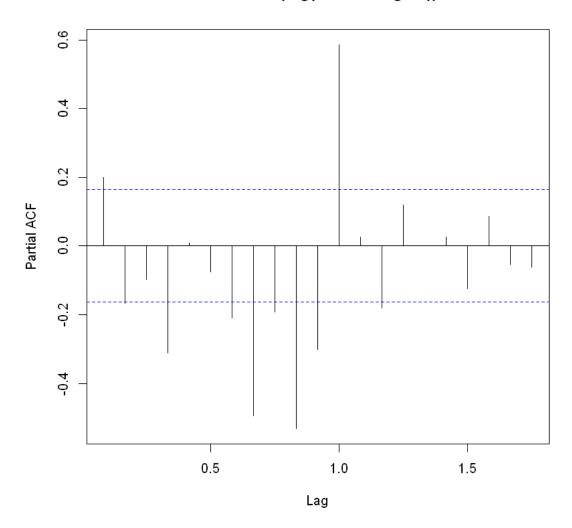

Series diff(log(AirPassengers))

Partial auto correlation function, as the word suggests, is partial not complete. Here again we are plot the correlations at various lags 1,2,3 BUT after adjusting for the effects of intermediate numbers.

[25]: pacf(diff(log(AirPassengers)))

Series diff(log(AirPassengers))

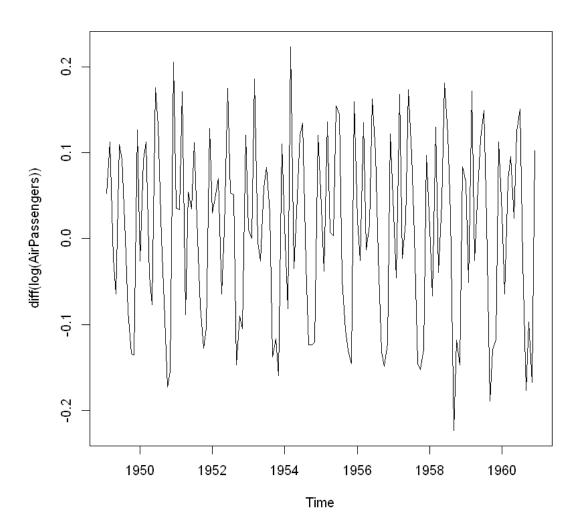

It determine value of p (value we got as 0)

d is number of time you do the differentiations to make the mean

We do diff only one time so value of d is 1

[26]: plot(diff(log(AirPassengers)))

0.6 ARIMA MODEL PREDICTION

```
[27]: fit <- arima(log(AirPassengers),c(0,1,1),seasonal =_⊔

→list(order=c(0,1,1),period=12))
```

[28]: fit

Coefficients:

```
\begin{array}{cccc} & \text{ma1} & \text{sma1} \\ & -0.4018 & -0.5569 \\ \text{s.e.} & 0.0896 & 0.0731 \end{array}
```

 $sigma^2$ estimated as 0.001348: log likelihood = 244.7, aic = -483.4

0.6.1 Predict for next 10 years

[29]: pred <- predict(fit,n.ahead=10*12) #10 years * 12 months
